Short lists with short programs in short time

Bruno Bauwens Anton Makhlin Nikolay Vereshchagin Marius Zimand

April 2013

▲□▶ ▲□▶ ▲ 臣▶ ▲ 臣▶ ― 臣 … のへで

- U universal TM, U(p) = x, we say p is a program for x.
- $C(x) = \min\{|p| \mid p \text{ program for } x\}.$
- C(x) canonical example of an **uncomputable** function.
- ► Finding a shortest program for *x*: also uncomputable.
- **Our question:** Is it possible to compute a short list containing a short program for *x*?

< ロ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

• DEFINITION. p is a c-short program for x if U(p) = x and |p| = C(x) + c.

► DEFINITION. A function f is a list approximator for c-short programs if ∀x, f(x) is a finite list containing a c-short program for x.

▲□▶ ▲□▶ ▲ 臣▶ ▲ 臣▶ ― 臣 … のへで

Our results

- ► There exists a computable list approximator f for O(1)-short programs, with size O(n²).
- For any computable list approximator for *c*-short programs, size is $\Omega(n^2/c^2)$.

< ロ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

There exists a poly.-time computable list approximator for O(log n)-short programs, with size poly(n).

Our results

What about lists containing a shortest program? Answer: It depends on the universal machine.

► For some U, any computable list containing a shortest program for x has size 2^{n-O(1)}.

< ロ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

► For some U, there is a computable list containing a shortest program of size O(n²).

Upper bounds

Th. 1: There exists a computable list approximator f for O(1)-short programs with size $O(n^2)$. Th. 2 There exists a **poly time computable** list approximator for $O(\log n)$ -short programs, with size poly(n).

< ロ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

Bipartite graphs with online matching with overhead c.

Upper bounds Th. 1: There exists a computable list approximator f for O(1)-short programs with size $O(n^2)$. Th. 2 There exists a **poly time computable** list approximator for $O(\log n)$ -short programs, with size poly(n).

Bipartite graphs with online matching with overhead c.

Short lists - combinatorial characterization

Theorem

 \exists (poly time) computable G with on-line matching with overhead c and the matching strategy is computable

IFF

 \exists (poly time) computable list of size deg(x) containing a c + O(1)-short program for x

Proof. (\Rightarrow only)

- Enumerate strings in LEFT(G) as they are produced by U.
- Say, at step s, U(q) = x, with |q| = k.
- Make request (x, k).
- x is matched with y of length k + c.
- y is a program for x.

• Why: on input y, re-play the matching process till some left string is matched to it; output this left string, which will be x.

So when q is the shortest program for x, we get a program for x of length C(x) + c.

The list consists of x's neighbors in G.

How to build a graph with online matching

Focus first on requests of type (*, k) with fixed k.

DEFINITION. A bipartite graph G is a (K, K')-expander if every K left nodes have $\geq K'$ neighbors.

Lemma

Let G be a (K, K + 1)-expander. If 2K matching requests are made, then less than K are rejected.

< ロ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

Proof. If $|REJECTED| \ge K$, then $|N(REJECTED)| \ge K + 1$. But each node in N(REJECTED) has satisfied a request. So number of requests would be at least (K + 1)(satisfied) + K (rejected) = 2K + 1. Contradiction.

 $G_{n,k}$ - basic building brick.

 $G_{n,k}$ - basic building brick.

Can be built with the probabilistic method + exhaustive search.

If 2K online matching requests are made, < K are rejected (where $K=2^k)$

Satisfies all requests (x, k) with |x| = n, fixed k.

left degree = $(k - 1)(n + 1) = O(n^2)$.

 $\mathsf{overhead} = 1$

 $H_n = H_{n,n} \cup H_{n,n-1} \cup \ldots \cup H_{n,1}$

Satisfies all requests (x, k), |x| = n, $k \le n$.

left degree = $O(n^3)$.

 $\mathsf{overhead} = 1$

```
H_n = H_{n,n} \cup H_{n,n-1} \cup \ldots \cup H_{n,1}
Satisfies all requests (x, k), |x| = n, k \le n.
left degree = O(n^3).
overhead = 1
```

 $H = H_1 \cup H_2 \cup \ldots \cup H_n \cup \ldots$, but append to each right node in H_n a code for n

< ロ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

Satisfies all requests

left degree(x) = $O(|x|^3)$.

overhead $O(\log n)$ (due to codes).

 $H_n = H_{n,n} \cup H_{n,n-1} \cup \ldots \cup H_{n,1}$ Satisfies all requests (x, k), |x| = n, $k \le n$. left degree = $O(n^3)$. overhead = 1

 $H = H_1 \cup H_2 \cup \ldots \cup H_n \cup \ldots$, but append to each right node in H_n a code for n

Satisfies all requests

```
left degree(x) = O(|x|^3).
```

overhead $O(\log n)$ (due to codes).

With a more elaborate construction, left degree (x) = $O(|x|^2)$, overhead = O(1). So :

Th. 1: There exists a computable list approximator f for O(1)-short programs, with size $O(n^2)$

- Use [Ta-Shma, Umans, Zuckerman'07] disperser:
- $L = \{0, 1\}^n, R = \{0, 1\}^{k O(\log n)}, \deg = \operatorname{poly}(n)$
- every $A \subseteq L, |A| = K \Rightarrow |N(A)| \ge \frac{1}{2}|R| = \frac{K}{2\mathrm{poly}(n)}$
- We take poly(n) copies of R to get (K, K+1)-expander.

- Use [Ta-Shma, Umans, Zuckerman'07] disperser:
- $L = \{0, 1\}^n, R = \{0, 1\}^{k O(\log n)}, \deg = \operatorname{poly}(n)$
- every $A \subseteq L, |A| = K \Rightarrow |N(A)| \ge \frac{1}{2}|R| = \frac{K}{2\text{poly}(n)}$
- We take poly(n) copies of R to get (K, K + 1)-expander. So:

Th. 2 There exists a **poly time computable** list approximator for $O(\log n)$ -short programs with size poly(n).

[Teutsch 2012] overhead O(1), so list has O(1)-short programs - arxiv 1212.0682

[Zimand 2013] simpler, shorter proof, list size = $n^{6+\epsilon}$

Short lists with short programs in short time - a short proof - arxiv 1302.1109

<ロト 4 目 ト 4 日 ト 4 日 ト 1 日 9 9 9 9</p>

Lower bounds - 1

Th. If a computable list contains a c-short program for x, then its size is $\Omega(n^2/(c+O(1))^2)$.

- $x \to \text{list } f(x) = \{y_1, \dots, y_t\}$ contains a *c*-short program for *x*.
- bipartite G: LEFT = $\{0,1\}^n$, $\forall x \in LEFT$, $(x, y_i) \in E$ for all $y_i \in f(x)$.
- G has on-line matching with overhead $c \Rightarrow$ also has off-line matching with overhead c.
- $G[\ell, k]$ is G from which we cut right nodes y with $|y| < \ell$ or |y| > k.
- $\forall k, G[0, k + c]$ is $(2^k, 2^k)$ -expander
- So, $\forall k, G[k-1, k+c]$ is $(2^k, 2^{k-1}+1)$ -expander.

LEMMA

Graph G has $|LEFT| = 2^{\ell}$, $|RIGHT| = 2^{k+c}$, and is a $(2^k, 2^{k-1} + 1)$ -expander. Then $\exists x \in LEFT$ with $deg(x) \ge \min(2^{k-2}, \frac{\ell-k}{c+2})$.

• Take
$$k \in (n/4, n/2]$$
. By LEMMA
(with $\ell = 3n/4$), in $G[k - 1, k + c]$,
all $x \in LEFT$, except $2^{3n/4}$, have
 $deg(x) \geq \frac{n}{4(c+3)}$.

< ロ > < 四 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

€ 990

• Take $k \in (n/4, n/2]$. By LEMMA (with $\ell = 3n/4$), in G[k - 1, k + c], all $x \in LEFT$, except $2^{3n/4}$, have $deg(x) \ge \frac{n}{4(c+3)}$.

• Pick $n/4 < k_1 < k_2 < \ldots < k_s < n/2$, and (c + 2) apart from each other; $s \approx \frac{n}{4(c+2)}$.

• In each $G[k_i - 1, k_i + c]$, all left nodes, except $2^{3n/4}$, have deg $\geq \frac{n}{4(c+3)}$.

• The RIGHT sets are disjoint.

• So,
$$\exists x \in LEFT$$
, with $deg(x) \geq s \cdot \frac{n}{4(c+3)} = \Omega(\frac{n^2}{(c+3)^2}).$

Dac

Lower Bounds - 2

Th. For some U, any list containing a shortest program for x has size $2^{\Omega(n)}$.

$$f(x) = \text{the list} = \{y_1, \dots, y_{|f(x)|}\}$$
 containing x^* -shortest program for x .
Clearly $C(x^* \mid x) \leq \log |f(x)| + O(1)$.

Would like $C(x^* \mid x)$ to be big, but $C(x^* \mid x) \leq \log n + O(1)$.

Use CT - total conditional complexity.

 $CT(u \mid v) = \min\{|p| \mid U(p, v) = u \text{ and } U(p, w) \downarrow \text{ for all } w.$

We still have $CT(x^* \mid x) \leq \log |f(x)| + O(1)$.

We show: $\exists U_0$, for infinitely many x, every shortest program p for x w.r.t. U_0 , $CT(p \mid x) \ge n - O(1)$.

So, $|f(x)| \ge 2^{n-O(1)}$.

(a) p is the unique shortest program for x w.r.t V,

(b)
$$C_U(x) \ge n-3$$

(c) $CT_U(0p \mid x) \ge n-3$.

(a) p is the unique shortest program for x w.r.t V,

(b)
$$C_U(x) \ge n-3$$

(c)
$$CT_U(0p \mid x) \ge n-3$$
.

Next define U_0 :

- (1) $U_0(0q) = V(q)$,
- (2) $U_0(1^5q) = U(q)$ (so U_0 is a standard universal machine).

(a) p is the unique shortest program for x w.r.t V,

(b)
$$C_U(x) \ge n-3$$

(c) $CT_U(0p \mid x) \ge n-3$.

Next define U_0 :

(1)
$$U_0(0q) = V(q)$$
,
(2) $U_0(1^5q) = U(q)$ (so U_0 is a standard universal machine).

Then,

$$\begin{split} & U_0(0p) = V(p) = x \\ & 0p \text{ is the unique shortest program for } x \text{ w.r.t. } U_0 \\ & CT_U(0p \mid x) \geq n-3. \end{split}$$

▲□▶ ▲□▶ ▲ 臣▶ ▲ 臣▶ ― 臣 … のへで

(a) p is the unique shortest program for x w.r.t V,

(b)
$$C_U(x) \ge n-3$$

(c) $CT_U(0p \mid x) \ge n-3$.

V on inputs of length *n*; $N = 2^n$; use $N \times N$ board.

BLACK can pass, or disable all cells in a column

V on inputs of length *n*; $N = 2^n$; use $N \times N$ board.

	×1	×2	•	•	•	•	•	×N
P1		Х	X					
P2	х	х 🔴	Х	Х	Х	Х	Х	Х
:	x	х						
				~				
-								
PN		Х					X	

WHITE can pass or put a pawn, but only one in a row or a column. WHITE moves define V: pawn placed on $(p, x) \Rightarrow V(p) = x$.

BLACK can pass, or disable all cells in a column, or disable a cell in each column.

< ロ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

V on inputs of length *n*; $N = 2^n$; use $N \times N$ board.

WHITE can pass or put a pawn, but only one in a row or a column. WHITE moves define V: pawn placed on $(p, x) \Rightarrow V(p) = x$.

BLACK can pass, or disable all cells in a column, or disable a cell in each column.

BLACK can do < N/4 disabling moves.

WHITE loses if at some point, after her turn, all pawns are in disabled cells.

WHITE has a winning strategy (later).

Build V s.t. for every
$$n$$
, $\exists p, x, |p| = |x| = n$:

(a)
$$p$$
 is the unique shortest program for x w.r.t V ,

(b)
$$C_U(x) \ge n-3$$

(c)
$$CT_U(0p \mid x) \ge n-3$$
.

Consider the following BLACK's blind strategy:

(a) Enumerate all strings x of length n with $C_U(x) < n-3$ (b) and all q, |q| < n-3 s.t. $U(q, x) \downarrow$ for all strings x of length

n.

At step s: if (a) happens, disable column x. if (b) happens, disable all cells (p, x) s.t. U(q, x) = 0p.

BLACK does $< 2^{n-3} + 2^{n-3} = N/4$ moves. WHITE moves define V: pawn placed on $(p, x) \Rightarrow V(p) = x$. WHITE wins: some cell (p, x) has pawn and is not disabled. Then (p, x) satisfies (a), (b), (c).

WHITE's winning strategy

(1) Initially, put a pawn on any cell

(2) When that cell gets disabled, put another pawn in an available cell.

BLACK makes < N/4 moves, so WHITE makes $\le N/4$ moves At each move, BLACK disables N cells At each WHITE's move, (2N - 1) cells become unavailable (row + col) So, total number of unavailable cells is:

$$\leq (N/4)N + N/4(2N-1) < N^2/4 + N^2/2 < N^2$$

< ロ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

So WHITE can always place a pawn.

SUMMARY

- ► One can compute a O(n²)-sized list containing a O(1)-short program.
- Any computable list containing a O(1)-short program has size Ω(n²).
- One can compute in poly time a poly(n)-sized list containing a O(log n)-short program.
- For some universal TM, any computable list containing a shortest program has size Ω(2ⁿ).
- ► There exists a universal TM, with a computable O(n²)-sized list containing a shortest program.

Thank you.
